

16-Bit 8-/16-Channel $\Delta\Sigma$ ADC with PGA and Easy Drive Input Current Cancellation

FEATURES

- Up to 8 Differential or 16 Single-Ended Inputs
- Easy Drive™ Technology Enables Rail-to-Rail Inputs with Zero Differential Input Current
- Directly Digitizes High Impedance Sensors with Full Accuracy
- 600nV RMS Noise
- Programmable Gain from 1 to 256
- Integrated High Accuracy Temperature Sensor
- GND to V_{CC} Input/Reference Common Mode Range
- Programmable 50Hz, 60Hz or Simultaneous 50Hz/60Hz Rejection Mode
- 2ppm INL, No Missing Codes
- 1ppm Offset and 15ppm Full-Scale Error
- 2x Speed Mode/Reduced Power Mode (15Hz Using Internal Oscillator and 80 μ A at 7.5Hz Output)
- No Latency: Digital Filter Settles in a Single Cycle, Even After a New Channel Is Selected
- Single-Supply 2.7V to 5.5V Operation
- Internal Oscillator
- Tiny 5mm \times 7mm QFN Package

APPLICATIONS

- Direct Sensor Digitizer
- Direct Temperature Measurement
- Instrumentation
- Industrial Process Control

DESCRIPTION

The LTC[®]2494 is a 16-channel (8-differential), 16-bit, No Latency $\Delta\Sigma$ ™ ADC with Easy Drive technology. The patented sampling scheme eliminates dynamic input current errors and the shortcomings of on-chip buffering through automatic cancellation of differential input current. This allows large external source impedances, and rail-to-rail input signals to be directly digitized while maintaining exceptional DC accuracy.

The LTC2494 includes programmable gain, a high accuracy temperature sensor and an integrated oscillator. This device can be configured to measure an external signal (from combinations of 16 analog input channels operating in single-ended or differential modes) or its internal temperature sensor. The integrated temperature sensor offers 1/2°C resolution and 2°C absolute accuracy. The LTC2494 can be configured to provide a programmable gain from 1 to 256 in 8 steps.

The LTC2494 allows a wide common mode input range (0V to V_{CC}), independent of the reference voltage. Any combination of single-ended or differential inputs can be selected and the first conversion, after a new channel is selected, is valid.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: All voltage values are with respect to GND.

Note 3: $V_{\text{CC}} = 2.7\text{V}$ to 5.5V unless otherwise specified.

$$V_{\text{REFCM}} = V_{\text{REF}}/2, f_s = 0.5V_{\text{REF}}/\text{Gain}$$

$$V_{\text{IN}} = \text{IN}^+ - \text{IN}^-, V_{\text{IN(CM)}} = (\text{IN}^+ + \text{IN}^-)/2,$$

where IN^+ and IN^- are the selected input channels.

Note 4: Use internal conversion clock or external conversion clock source with $f_{\text{EOSC}} = 307.2\text{kHz}$ unless otherwise specified.

Note 5: Guaranteed by design, not subject to test.

Note 6: Integral nonlinearity is defined as the deviation of a code from a straight line passing through the actual endpoints of the transfer curve. The deviation is measured from the center of the quantization band.

Note 7: 50Hz mode (internal oscillator) or $f_{\text{EOSC}} = 256\text{kHz} \pm 2\%$ (external oscillator).

Note 8: 60Hz mode (internal oscillator) or $f_{\text{EOSC}} = 307.2\text{kHz} \pm 2\%$ (external oscillator).

Note 9: Simultaneous 50Hz/60Hz mode (internal oscillator) or $f_{\text{EOSC}} = 280\text{kHz} \pm 2\%$ (external oscillator).

Note 10: The SCK can be configured in external SCK mode or internal SCK mode. In external SCK mode, the SCK pin is used as a digital input and the driving clock is f_{ESCK} . In the internal SCK mode, the SCK pin is used as a digital output and the output clock signal during the data output is f_{ISCK} .

Note 11: The external oscillator is connected to the f_0 pin. The external oscillator frequency, f_{EOSC} , is expressed in kHz.

Note 12: The converter uses its internal oscillator.

Note 13: The output noise includes the contribution of the internal calibration operations.

Note 14: Guaranteed by design and test correlation.

Note 15: The converter is in external SCK mode of operation such that the SCK pin is used as a digital input. The frequency of the clock signal driving SCK during the data output is f_{ESCK} and is expressed in Hz.

Note 16: Refer to Applications Information section for performance vs data rate graphs.

Note 17: The converter is in internal SCK mode of operation such that the SCK pin is used as a digital output.

Note 18: For $V_{\text{CC}} < 3\text{V}$, V_{IH} is 2.5V for Pin f_0 .

TYPICAL PERFORMANCE CHARACTERISTICS

PIN FUNCTIONS

GND (Pins 1, 3, 4, 5, 6, 31, 32, 33): Ground. Multiple ground pins internally connected for optimum ground current flow and V_{CC} decoupling. Connect each one of these pins to a common ground plane through a low impedance connection. All eight pins must be connected to ground for proper operation.

NC (Pin 2): No Connection. This pin can be left floating or tied to GND.

COM (Pin 7): The Common Negative Input (IN^-) for All Single-Ended Multiplexer Configurations. The voltage on CH0 to CH15 and COM pins can have any value between $GND - 0.3V$ to $V_{CC} + 0.3V$. Within these limits, the two selected inputs (IN^+ and IN^-) provide a bipolar input range $V_{IN} = (IN^+ - IN^-)$ from $-0.5 \cdot V_{REF}/Gain$ to $0.5 \cdot V_{REF}/Gain$. Outside this input range, the converter produces unique overrange and underrange output codes.

CH0 to CH15 (Pins 8 to 23): Analog Inputs. May be programmed for single-ended or differential mode.

MUXOUTP (Pin 24): Positive Multiplexer Output. Used to drive an external buffer/amplifier or can be shorted directly to ADCINP.

ADCINP (Pin 25): Positive ADC Input. Tie to the output of a buffer/amplifier driven by MUXOUTP or tie directly to MUXOUTP.

ADCINN (Pin 26): Negative ADC Input. Tie to the output of a buffer/amplifier driven by MUXOUTN or tie directly to MUXOUTN.

MUXOUTN (Pin 27): Negative Multiplexer Output. Used to drive an external buffer/amplifier or can be shorted directly to ADCINN.

V_{CC} (Pin 28): Positive Supply Voltage. Bypass to GND with a $10\mu F$ tantalum capacitor in parallel with a $0.1\mu F$ ceramic capacitor as close to the part as possible.

REF^+ (Pin 29), REF^- (Pin 30): Differential Reference Input. The voltage on these pins can have any value between GND and V_{CC} as long as the reference positive input, REF^+ , remains more positive than the negative reference input, REF^- , by at least $0.1V$. The differential voltage $V_{REF} = (REF^+ - REF^-)$ sets the full-scale range ($-0.5 \cdot V_{REF}/Gain$ to $0.5 \cdot V_{REF}/Gain$) for all input channels. When performing an on-chip temperature measurement, the minimum value of $REF = 2V$.

CONVERTER OPERATION

Converter Operation Cycle

The LTC2494 is a multichannel, low power, delta-sigma, analog-to-digital converter with an easy to use, 4-wire interface and automatic differential input current cancellation. Its operation is made up of four states (See Figure 2). The converter's operating cycle begins with the conversion, followed by the sleep state, and ends with the data input/output cycle. The 4-wire interface consists of serial data output (SDO), serial clock (SCK), chip select (\overline{CS}) and serial data input (SDI). The interface, timing, operation cycle and data output format is compatible with Linear's entire family of $\Delta\Sigma$ converters.

Initially, at power-up, the LTC2494 performs a conversion. Once the conversion is complete, the device enters the sleep state. While in this sleep state, if \overline{CS} is HIGH, power consumption is reduced by two orders of magnitude. The part remains in the sleep state as long as \overline{CS} is HIGH. The conversion result is held indefinitely in a static shift register while the part is in the sleep state.

Once \overline{CS} is pulled LOW, the device powers up, exits the sleep state, and enters the data input/output state. If \overline{CS} is brought HIGH before the first rising edge of SCK, the device returns to the sleep state and the power is reduced. If \overline{CS} is brought HIGH after the first rising edge of SCK, the

data output cycle is aborted and a new conversion cycle begins. The data output corresponds to the conversion just completed. This result is shifted out on the serial data output pin (SDO) under the control of the serial clock pin (SCK). Data is updated on the falling edge of SCK allowing the user to reliably latch data on the rising edge of SCK (see Figure 3). The configuration data for the next conversion is also loaded into the device at this time. Data is loaded from the serial data input pin (SDI) on each rising edge of SCK. The data input/output cycle is concluded once 24 bits are read out of the ADC or when \overline{CS} is brought HIGH. The device automatically initiates a new conversion and the cycle repeats.

Through timing control of the \overline{CS} and SCK pins, the LTC2494 offers several flexible modes of operation (internal or external SCK and free-running conversion modes). These various modes do not require programming and do not disturb the cyclic operation described above. These modes of operation are described in detail in the Serial Interface Timing Modes section.

Ease of Use

The LTC2494 data output has no latency, filter settling delay, or redundant data associated with the conversion cycle. There is a one-to-one correspondence between the conversion and the output data. Therefore, multiplexing multiple analog inputs is straightforward. Each conversion, immediately following a newly selected input or mode, is valid and accurate to the full specifications of the device.

The LTC2494 automatically performs offset and full-scale calibration every conversion cycle independent of the input channel selected. This calibration is transparent to the user and has no effect with the operation cycle previously described. The advantage of continuous calibration is extreme stability of offset and full-scale readings with respect to time, supply voltage variation, input channel and temperature drift.

Easy Drive Input Current Cancellation

The LTC2494 combines a high precision, delta-sigma ADC with an automatic, differential, input current cancellation front end. A proprietary front end passive sampling network transparently removes the differential input current.

Figure 2. LTC2494 State Transition Diagram

APPLICATIONS INFORMATION

This enables external RC networks and high impedance sensors to directly interface to the LTC2494 without external amplifiers. The remaining common mode input current is eliminated by either balancing the differential input impedances or setting the common mode input equal to the common mode reference (see the Automatic Differential Input Current Cancellation section). This unique architecture does not require on-chip buffers, thereby enabling signals to swing beyond ground or up to V_{CC} . Moreover, the cancellation does not interfere with the transparent offset and full-scale auto-calibration and the absolute accuracy (full-scale + offset + linearity + drift) is maintained even with external RC networks.

Power-Up Sequence

The LTC2494 automatically enters an internal reset state when the power supply voltage, V_{CC} , drops below approximately 2V. This feature guarantees the integrity of the conversion result, input channel selection and serial clock mode.

When V_{CC} rises above this threshold, the converter creates an internal power-on reset (POR) signal with a duration of approximately 4ms. The POR signal clears all internal registers. The conversion immediately following a POR cycle is performed on the input channels $IN^+ = CH0$ and $IN^- = CH1$ with simultaneous 50Hz/60Hz rejection $1\times$ output rate, and gain = 1. The first conversion following a POR cycle is accurate within the specification of the device if the power supply voltage is restored to (2.7V to 5.5V) before the end of the POR interval. A new input channel, rejection mode, speed mode, temperature selection, or gain can be programmed into the device during this first data input/output cycle.

Reference Voltage Range

This converter accepts a truly differential external reference voltage. The absolute/common mode voltage range for the REF^+ and REF^- pins covers the entire operating range of the device (GND to V_{CC}). For correct converter operation, V_{REF} must be positive ($REF^+ > REF^-$).

The LTC2494 differential reference input range is 0.1V to V_{CC} . For the simplest operation, REF^+ can be shorted to V_{CC} and REF^- can be shorted to GND. The converter output noise is determined by the thermal noise of the front end circuits, and as such, its value in nanovolts is nearly constant with reference voltage. A decrease in reference voltage will not significantly improve the converter's effective resolution. On the other hand, a decreased reference will improve the converter's overall INL performance.

Input Voltage Range

The LTC2494 input measurement range is $-0.5 \cdot V_{REF}$ to $+0.5 \cdot V_{REF}$ in both differential and single-ended configurations as shown in Figure 39. Highest linearity is achieved with Fully Differential drive and a constant common mode voltage (Figure 39b). Other drive schemes may incur an INL error of approximately 50ppm. This error can be calibrated out using a three point calibration and a second-order curve fit.

The analog input is truly differential with an absolute, common mode range for $CH0$ to $CH15$ and COM input pins extending from $GND - 0.3V$ to $V_{CC} + 0.3V$. Outside these limits, the ESD protection devices begin to turn on and the errors due to input leakage current increase rapidly. Within these limits, the LTC2494 converts the bipolar differential input signal $V_{IN} = IN^+ - IN^-$ (where IN^+ and IN^- are the selected input channels), from $-FS = -0.5 \cdot V_{REF}/Gain$ to $+FS = 0.5 \cdot V_{REF}/Gain$ where $V_{REF} = REF^+ - REF^-$. Outside this range, the converter indicates the overrange or the underrange condition using distinct output codes.

Signals applied to the input ($CH0$ to $CH15$, COM) may extend 300mV below ground and above V_{CC} . In order to limit any fault current, resistors of up to 5k may be added in series with the input. The effect of series resistance on the converter accuracy can be evaluated from the curves presented in the Input Current/Reference Current sections. In addition, series resistors will introduce a temperature dependent error due to input leakage current. A 1nA input leakage current will develop a 1ppm offset error on a 5k resistor if $V_{REF} = 5V$. This error has a very strong temperature dependency.

APPLICATIONS INFORMATION

MUXOUT/ADCIN

The output of the multiplexer (MUXOUT) and the input to the ADC (ADCIN) can be used to perform input signal conditioning on any of the selected input channels or simply shorted together for direct digitization. If an external amplifier is used, the LTC2494 automatically calibrates both the offset and drift of this circuit and the Easy Drive sampling scheme enables a wide variety of amplifiers to be used.

In order to achieve optimum performance, if an external amplifier is not used, short these pins directly together (ADCINP to MUXOUTP and ADCINN to MUXOUTN) and minimize their capacitance to ground.

SERIAL INTERFACE PINS

The LTC2494 transmits the conversion result, reads the input configuration, and receives a START of conversion command through a synchronous 3- or 4-wire interface. During the conversion and sleep states, this interface can be used to access the converter status. During the data output state, it is used to read the conversion result, program the input channel, rejection frequency, speed multiplier, select the temperature sensor and set the gain.

Serial Clock Input/Output (SCK)

The serial clock pin (SCK) is used to synchronize the data input/output transfer. Each bit is shifted out of the SDO pin on the falling edge of SCK and data is shifted into the SDI pin on the rising edge of SCK.

The serial clock pin (SCK) can be configured as either a master (SCK is an output generated internally) or a slave (SCK is an input and applied externally). Master mode (internal SCK) is selected by simply floating the SCK pin. Slave mode (external SCK) is selected by driving SCK LOW during power-up and each falling edge of \overline{CS} . Specific details of these SCK modes are described in the Serial Interface Timing Modes section.

Serial Data Output (SDO)

The serial data output pin (SDO) provides the result of the last conversion as a serial bit stream (MSB first) during

the data output state. In addition, the SDO pin is used as an end of conversion indicator during the conversion and sleep states.

When \overline{CS} is HIGH, the SDO driver is switched to a high impedance state in order to share the data output line with other devices. If \overline{CS} is brought LOW during the conversion phase, the EOC bit (SDO pin) will be driven HIGH. Once the conversion is complete, if \overline{CS} is brought LOW, \overline{EOC} will be driven LOW indicating the conversion is complete and the result is ready to be shifted out of the device.

Chip Select (\overline{CS})

The active LOW \overline{CS} pin is used to test the conversion status, enable I/O data transfer, initiate a new conversion, control the duration of the sleep state and set the SCK mode.

At the conclusion of a conversion cycle, while \overline{CS} is HIGH, the device remains in a low power sleep state where the supply current is reduced several orders of magnitude. In order to exit the sleep state and enter the data output state, \overline{CS} must be pulled LOW. Data is now shifted out the SDO pin under control of the SCK pin as described previously.

A new conversion cycle is initiated either at the conclusion of the data output cycle (all 24 data bits read) or by pulling \overline{CS} HIGH any time between the first and 24th rising edges of the serial clock (SCK). In this case, the data output is aborted and a new conversion begins.

Serial Data Input (SDI)

The serial data input (SDI) is used to select the input channel, rejection frequency, speed multiplier, gain, and to access the integrated temperature sensor. Data is shifted into the device during the data output/input state on the rising edge of SCK while \overline{CS} is LOW.

OUTPUT DATA FORMAT

The LTC2494 serial output stream is 24 bits long. The first bit indicates the conversion status, the second bit is always zero, and the third bit conveys sign information. The next 17 bits are the conversion result, MSB first. The remaining 4 bits are always LOW.

Bit 23 (first output bit) is the end of conversion (\overline{EOC}) indicator. This bit is available on the SDO pin during the

APPLICATIONS INFORMATION

conversion and sleep states whenever \overline{CS} is LOW. This bit is HIGH during the conversion cycle, goes LOW once the conversion is complete, and is Hi-Z when \overline{CS} is HIGH.

Bit 22 (second output bit) is a dummy bit (DMY) and is always LOW.

Bit 21 (third output bit) is the conversion result sign indicator (SIG). If the selected input ($V_{IN} = IN^+ - IN^-$) is greater than or equal to 0V, this bit is HIGH. If $V_{IN} < 0$, this bit is LOW.

Bit 20 (fourth output bit) is the most significant bit (MSB) of the result. This bit in conjunction with Bit 21 also provides underrange and overrange indication. If both Bit 21 and Bit 20 are HIGH, the differential input voltage is above +FS. If both Bit 21 and Bit 20 are LOW, the differential input voltage is below -FS. The function of these bits is summarized in Table 1.

Table 1. LTC2494 Status Bits

Input Range	Bit 23 EOC	Bit 22 DMY	Bit 21 SIG	Bit 20 MSB
$V_{IN} \geq 0.5 \cdot V_{REF}/Gain$	0	0	1	1
$0V \leq V_{IN} < 0.5 \cdot V_{REF}/Gain$	0	0	1/0	0
$-0.5 \cdot V_{REF}/Gain \leq V_{IN} < 0V$	0	0	0	1
$V_{IN} < -0.5 \cdot V_{REF}/Gain$	0	0	0	0

Bits 20 to 4 are the 16-bit plus sign conversion result MSB first.

Bit 4 is the least significant bit (LSB_{16}).

Bits 3 to 0 are always LOW.

Data is shifted out of the SDO pin under control of the serial clock (SCK) (see Figure 3). Whenever \overline{CS} is HIGH, SDO remains high impedance and SCK is ignored.

In order to shift the conversion result out of the device, \overline{CS} must first be driven LOW. \overline{EOC} is seen at the SDO pin of the device once \overline{CS} is pulled LOW. \overline{EOC} changes in real time from HIGH to LOW at the completion of a conversion. This signal may be used as an interrupt for an external microcontroller. Bit 23 (\overline{EOC}) can be captured on the first rising edge of SCK. Bit 22 is shifted out of the device on the first falling edge of SCK. The final data bit (Bit 0) is shifted out on the on the falling edge of the 23rd SCK and may be latched on the rising edge of the 24th SCK pulse. On the falling edge of the 24th SCK pulse, SDO goes HIGH indicating the initiation of a new conversion cycle. This bit serves as \overline{EOC} (Bit 23) for the next conversion cycle. Table 2 summarizes the output data format.

As long as the voltage on the IN^+ and IN^- pins remains between $-0.3V$ and $V_{CC} + 0.3V$ (absolute maximum operating range) a conversion result is generated for any differential input voltage V_{IN} from $-FS = -0.5 \cdot V_{REF}/Gain$ to $+FS = 0.5 \cdot V_{REF}/Gain$. For differential input voltages greater than +FS, the conversion result is clamped to the value corresponding to +FS + 1LSB. For differential input voltages below -FS, the conversion result is clamped to the value -FS - 1LSB.

INPUT DATA FORMAT

The LTC2494 serial input word is 16 bits long and contains two distinct sets of data. The first set (SGL, ODD, A2, A1, A0) is used to select the input channel. The second set of data (IM, FA, FB, SPD, GS2, GS1, GS0) is used to select the frequency rejection, speed mode (1x, 2x), temperature measurement and gain.

After power-up, the device initiates an internal reset cycle which sets the input channel to CH0–CH1 ($IN^+ = CH0$, $IN^- = CH1$), the frequency rejection to simultaneous 50Hz/60Hz, 1x output rate (auto-calibration enabled), and gain = 1. The first conversion automatically begins at power-up using this default configuration. Once the conversion is complete, a new word may be written into the device.

The first three bits shifted into the device consist of two preamble bits and an enable bit. These bits are used to enable the device configuration and input channel selection. Valid settings for these three bits are 000, 100 and 101. Other combinations should be avoided. If the first three bits are 000 or 100, the following data is ignored (don't care) and the previously selected input channel and configuration remain valid for the next conversion.

If the first three bits shifted into the device are 101, then the next five bits select the input channel for the next conversion cycle (see Table 3).

The first input bit following the 101 sequence (SGL) determines if the input selection is differential (SGL = 0) or single-ended (SGL = 1). For SGL = 0, two adjacent channels can be selected to form a differential input. For SGL = 1, one of 16 channels is selected as the positive input. The negative input is COM for all single-ended operations. The remaining 4 bits (ODD, A2, A1, A0) determine which channel(s) is/are selected and the polarity (for a differential input).

The next serial input bit immediately following the input channel selection is the enable bit for the conversion configuration (EN2). If this bit is set to 0, then the next conversion is performed using the previously selected converter configuration. This is useful in systems using the same rejection/speed for all input channels and for backward compatibility with the LTC2418/LTC2414 families of delta-sigma ADCs.

The second set of configuration data can be loaded into the device by setting $EN2 = 1$ (see Table 4). The first bit (IM) is used to select the internal temperature sensor. If $IM = 1$, the following conversion will be performed on the internal temperature sensor rather than the selected input channel. The next 2 bits (FA and FB) are used to set the rejection frequency. The next bit (SPD) is used to select either the 1x output rate if $SPD = 0$ (auto-calibration is enabled and the offset is continuously calibrated and removed from the final conversion result) or the 2x output rate if SPD

= 1 (offset calibration disabled, multiplexing output rates up to 15Hz with no latency). When IM = 1 (temperature measurement), SPD, GS2, GS1, GS0 will be ignored and the device will operate in 1x mode. The final 3 bits (GS2, GS1, GS0) are used to select the gain. The configuration remains valid until a new input word with EN = 1 (the first 3 bits are 101) and EN2 = 1 is shifted into the device.

Rejection Mode (FA, FB)

The LTC2494 includes a high accuracy on-chip oscillator with no required external components. Coupled with an integrated 4th order digital low pass filter, the LTC2494 rejects line frequency noise. In the default mode, the LTC2494 simultaneously rejects 50Hz and 60Hz by at least 87dB. If more rejection is required, the LTC2494 can be configured to reject 50Hz or 60Hz to better than 110dB.

Speed Mode (SPD)

Every conversion cycle, two conversions are combined to remove the offset (default mode). This result is free from offset and drift. In applications where the offset is not critical, the auto-calibration feature can be disabled with the benefit of twice the output rate. While operating in the 2x mode (SPD = 1), the linearity and full-scale errors are unchanged from the 1x mode performance. In both the 1x and 2x mode there is no latency. This enables input steps or multiplexer changes to settle in a single conversion cycle easing system overhead and increasing the effective conversion rate. During temperature measurements, the 1x mode is always used independent of the value of SPD.

GAIN (GS2, GS1, GS0)

The input referred gain of the LTC2494 is adjustable from 1 to 256 (see Tables 5a and 5b). With a gain of 1, the differential input range is $\pm V_{REF}/2$ and the common mode input range is rail-to-rail. As the gain is increased, the differential input range is reduced to $\pm 0.5 \cdot V_{REF}/\text{Gain}$ but the common mode input range remains rail-to-rail. As the differential gain is increased, low level voltages are digitized with greater resolution. At a gain of 256, the LTC2494 digitizes an input signal range of $\pm 9.76\text{mV}$ with over 16,000 counts.

Temperature Sensor

The LTC2494 includes an integrated temperature sensor. The temperature sensor is selected by setting $IM = 1$. During temperature readings, $MUXOUTN/MUXOUTP$ remains connected to the selected input channel. The ADC internally connects to the temperature sensor and performs a conversion.

The digital output is proportional to the absolute temperature of the device. This feature allows the converter to perform cold junction compensation for external thermocouples or continuously remove the temperature effects of external sensors.

The internal temperature sensor output is 28mV at 27°C (300°K), with a slope of 93.5μV/°C independent of V_{REF} . Slope calibration is not required if the reference voltage (V_{REF}) is known. A 5V reference has a slope of 2.45 LSBs₁₆/°C. The temperature is calculated from the output code (where $DATAOUT_{16}$ is the decimal representation of the 16-bit result) for a 5V reference using the following formula:

$$T_K = \text{DATAOUT}_{16} / 2.45 \text{ in Kelvin}$$

If a different value of V_{REF} is used, the temperature output is:

$$T_K = \text{DATAOUT}_{16} \cdot V_{REF} / 12.25 \text{ in Kelvin}$$

If the value of V_{REF} is not known, the slope is determined by measuring the temperature sensor at a known temperature T_N (in °K) and using the following formula:

$$\text{SLOPE} = \text{DATAOUT}_{16} / T_N$$

This value of slope can be used to calculate further temperature readings using:

$$T_K = \text{DATAOUT}_{16} / \text{SLOPE}$$

All Kelvin temperature readings can be converted to T_C (°C) using the fundamental equation:

$$T_C = T_K - 273$$

SERIAL INTERFACE TIMING MODES

The LTC2494's 4-wire interface is SPI and MICROWIRE compatible. This interface offers several flexible modes of operation. These include internal/external serial clock, 3- or 4-wire I/O, single cycle or continuous conversion. The following sections describe each of these timing modes in detail. In all cases, the converter can use the internal oscillator ($f_0 = \text{LOW}$) or an external oscillator connected to the f_0 pin. For each mode, the operating cycle, data input format, data output format and performance remain the same. Refer to Table 6 for a summary.

External Serial Clock, Single Cycle Operation

This timing mode uses an external serial clock to shift out the conversion result and $\overline{\text{CS}}$ to monitor and control the state of the conversion cycle (see Figure 6).

The external serial clock mode is selected during the power-up sequence and on each falling edge of $\overline{\text{CS}}$. In order to

enter and remain in the external SCK mode of operation, SCK must be driven LOW both at power-up and on each $\overline{\text{CS}}$ falling edge. If SCK is HIGH on the falling edge of $\overline{\text{CS}}$, the device will switch to the internal SCK mode.

The serial data output pin (SDO) is Hi-Z as long as $\overline{\text{CS}}$ is HIGH. At any time during the conversion cycle, $\overline{\text{CS}}$ may be pulled LOW in order to monitor the state of the converter. While $\overline{\text{CS}}$ is LOW, $\overline{\text{EOC}}$ is output to the SDO pin.

$\overline{\text{EOC}} = 1$ while a conversion is in progress and $\overline{\text{EOC}} = 0$ if the conversion is complete and the device is in the sleep state. Independent of $\overline{\text{CS}}$, the device automatically enters the sleep state once the conversion is complete; however, in order to reduce the power, $\overline{\text{CS}}$ must be HIGH.

When the device is in the sleep state, its conversion result is held in an internal static shift register. The device remains in the sleep state until the first rising edge of SCK is seen while $\overline{\text{CS}}$ is LOW. The input data is then shifted in via the SDI pin on each rising edge of SCK (including the first rising

edge). The channel selection and converter configuration mode will be used for the following conversion cycle. If the input channel or converter configuration is changed during this I/O cycle, the new settings take effect on the conversion cycle following the data input/output cycle. The output data is shifted out the SDO pin on each falling edge of SCK. This enables external circuitry to latch the output on the rising edge of SCK. \overline{EOC} can be latched on the first rising edge of SCK and the last bit of the conversion result can be latched on the 24th rising edge of SCK. On the 24th falling edge of SCK, the device begins a new conversion and SDO goes HIGH ($\overline{EOC} = 1$) indicating a conversion is in progress.

At the conclusion of the data cycle, \overline{CS} may remain LOW and \overline{EOC} monitored as an end-of-conversion interrupt.

Typically, \overline{CS} remains LOW during the data output/input state. However, the data output state may be aborted by

pulling \overline{CS} HIGH any time between the 1st falling edge and the 24th falling edge of SCK (see Figure 7). On the rising edge of \overline{CS} , the device aborts the data output state and immediately initiates a new conversion. In order to program a new input channel, 8 SCK clock pulses are required. If the data output sequence is aborted prior to the 8th falling edge of SCK, the new input data is ignored and the previously selected input channel remains valid. If the rising edge of \overline{CS} occurs after the 8th falling edge of SCK, the new input channel is loaded and valid for the next conversion cycle. If \overline{CS} goes HIGH between the 8th falling edge and the 16th falling edge of SCK, the new channel is still loaded, but the converter configuration remains unchanged. In order to program both the input channel and converter configuration, \overline{CS} must go HIGH after the 16th falling edge of SCK (at this point all data has been shifted into the device).

APPLICATIONS INFORMATION

External Serial Clock, 3-Wire I/O

This timing mode uses a 3-wire serial I/O interface. The conversion result is shifted out of the device by an externally generated serial clock (SCK) signal (see Figure 8). \overline{CS} is permanently tied to ground, simplifying the user interface or isolation barrier.

The external serial clock mode is selected at the end of the power-on reset (POR) cycle. The POR cycle is typically concluded 4ms after V_{CC} exceeds 2V. The level applied to SCK at this time determines if SCK is internally generated or externally applied. In order to enter the external SCK mode, SCK must be driven LOW prior to the end of the POR cycle.

Since \overline{CS} is tied LOW, the end-of-conversion (\overline{EOC}) can be continuously monitored at the SDO pin during the convert and sleep states. \overline{EOC} may be used as an interrupt to an external controller. $\overline{EOC} = 1$ while the conversion is in progress and $\overline{EOC} = 0$ once the conversion is complete. On the falling edge of \overline{EOC} , the conversion result

is loading into an internal static shift register. The output data can now be shifted out the SDO pin under control of the externally applied SCK signal. Data is updated on the falling edge of SCK. The input data is shifted into the device through the SDI pin on the rising edge of SCK. On the 24th falling edge of SCK, SDO goes HIGH, indicating a new conversion has begun. This data now serves as \overline{EOC} for the next conversion.

Internal Serial Clock, Single Cycle Operation

This timing mode uses the internal serial clock to shift out the conversion result and \overline{CS} to monitor and control the state of the conversion cycle (see Figure 9).

In order to select the internal serial clock timing mode, the serial clock pin (SCK) must be floating or pulled HIGH before the conclusion of the POR cycle and prior to each falling edge of \overline{CS} . An internal weak pull-up resistor is active on the SCK pin during the falling edge of \overline{CS} ; therefore, the internal SCK mode is automatically selected if SCK is not externally driven.

Figure 9. Internal Serial Clock, Single Cycle Operation

APPLICATIONS INFORMATION

The serial data output pin (SDO) is Hi-Z as long as \overline{CS} is HIGH. At any time during the conversion cycle, \overline{CS} may be pulled LOW in order to monitor the state of the converter. Once \overline{CS} is pulled LOW, SCK goes LOW and \overline{EOC} is output to the SDO pin. $\overline{EOC} = 1$ while the conversion is in progress and $\overline{EOC} = 0$ if the device is in the sleep state.

When testing \overline{EOC} , if the conversion is complete ($\overline{EOC} = 0$), the device will exit sleep state. In order to return to the sleep state and reduce the power consumption, \overline{CS} must be pulled HIGH before the device pulls SCK HIGH. When the device is using its own internal oscillator (f_0 is tied LOW), the first rising edge of SCK occurs $12\mu s$ ($t_{EOCTEST} = 12\mu s$) after the falling edge of \overline{CS} . If f_0 is driven by an external oscillator of frequency f_{EOSC} , then $t_{EOCTEST} = 3.6/f_{EOSC}$.

If \overline{CS} remains LOW longer than $t_{EOCTEST}$, the first rising edge of SCK will occur and the conversion result is shifted out the SDO pin on the falling edge of SCK. The serial input word (SDI) is shifted into the device on the rising edge of SCK.

After the 24th rising edge of SCK a new conversion automatically begins. SDO goes HIGH ($\overline{EOC} = 1$) and SCK remains HIGH for the duration of the conversion cycle. Once the conversion is complete, the cycle repeats.

Typically, \overline{CS} remains LOW during the data output state. However, the data output state may be aborted by pulling \overline{CS} HIGH any time between the 1st rising edge and the 24th falling edge of SCK (see Figure 10). On the rising edge of \overline{CS} , the device aborts the data output state and immediately initiates a new conversion. In order to program a new input channel, 8 SCK clock pulses are required. If the data output sequence is aborted prior to the 8th falling edge of SCK, the new input data is ignored and the previously selected input channel remains valid. If the rising edge of \overline{CS} occurs after the 8th falling edge of SCK, the new input channel is loaded and valid for the next conversion cycle. If \overline{CS} goes HIGH between the 8th falling edge and the 16th falling edge of SCK, the new channel is still loaded, but the converter configuration remains unchanged. In order to program

both the input channel and converter configuration, \overline{CS} must go HIGH after the 16th falling edge of SCK (at this point all data has been shifted into the device).

Internal Serial Clock, 3-Wire I/O, Continuous Conversion.

This timing mode uses a 3-wire interface. The conversion result is shifted out of the device by an internally generated serial clock (SCK) signal (see Figure 11). In this case, \overline{CS} is permanently tied to ground, simplifying the user interface or transmission over an isolation barrier.

The internal serial clock mode is selected at the end of the power-on reset (POR) cycle. The POR cycle is concluded approximately 4ms after V_{CC} exceeds 2V. An internal weak pull-up is active during the POR cycle; therefore, the internal serial clock timing mode is automatically selected if SCK is floating or driven HIGH.

During the conversion, the SCK and the serial data output pin (SDO) are HIGH ($\overline{EOC} = 1$). Once the conversion is complete, SCK and SDO go LOW ($\overline{EOC} = 0$) indicating

the conversion has finished and the device has entered the sleep state. The device remains in the sleep state a minimum amount of time (1/2 the internal SCK period) then immediately begins outputting and inputting data. The input data is shifted through the SDI pin on the rising edge of SCK (including the first rising edge) and the output data is shifted out the SDO pin on the falling edge of SCK. The data input/output cycle is concluded and a new conversion automatically begins after the 24th rising edge of SCK. During the next conversion, SCK and SDO remain HIGH until the conversion is complete.

The Use of a 10k Pull-Up on SCK for Internal SCK Selection

If \overline{CS} is pulled HIGH while the converter is driving SCK LOW, the internal pull-up is not available to restore SCK to a logic HIGH state if SCK is floating. This will cause the device to exit the internal SCK mode on the next falling edge of \overline{CS} . This can be avoided by adding an external 10k pull-up resistor to the SCK pin.

APPLICATIONS INFORMATION

Whenever SCK is LOW, the LTC2494's internal pull-up at SCK is disabled. Normally, SCK is not externally driven if the device is operating in the internal SCK timing mode. However, certain applications may require an external driver on SCK. If the driver goes Hi-Z after outputting a LOW signal, the internal pull-up is disabled. An external 10k pull-up resistor prevents the device from exiting the internal SCK mode under this condition.

A similar situation may occur during the sleep state when \overline{CS} is pulsed HIGH-LOW-HIGH in order to test the conversion status. If the device is in the sleep state ($\overline{EOC} = 0$), SCK will go LOW. If \overline{CS} goes HIGH before the time $t_{EOCtest}$, the internal pull-up is activated. If SCK is heavily loaded, the internal pull-up may not restore SCK to a HIGH state before the next falling edge of \overline{CS} . The external 10k pull-up resistor prevents the device from exiting the internal SCK mode under this condition.

PRESERVING THE CONVERTER ACCURACY

The LTC2494 is designed to reduce as much as possible sensitivity to device decoupling, PCB layout, anti-aliasing circuits, line frequency perturbations and temperature sensitivity. In order to achieve maximum performance a few simple precautions should be observed.

Digital Signal Levels

The LTC2494's digital interface is easy to use. Its digital inputs SDI, f_0 , \overline{CS} and SCK (in external serial clock mode) accept standard CMOS logic levels. Internal hysteresis circuits can tolerate edge transition times as slow as 100 μ s.

The digital input signal range is 0.5V to $V_{CC} - 0.5V$. During transitions, the CMOS input circuits draw dynamic current. For optimal performance, application of signals to the serial data interface should be reserved for the sleep and data output periods.

During the conversion period, overshoot and undershoot of fast digital signals applied to both the serial digital interface and the external oscillator pin (f_0) may degrade the converter performance. Undershoot and overshoot occur due to impedance mismatch of the circuit board trace at the converter pin when the transition time of an external control signal is less than twice the propagation

delay from the driver to the input pin. For reference, on a regular FR-4 board, the propagation delay is approximately 183ps/inch. In order to prevent overshoot, a driver with a 1ns transition time must be connected to the converter through a trace shorter than 2.5 inches. This becomes difficult when shared control lines are used and multiple reflections occur.

Parallel termination near the input pin of the LTC2494 will eliminate this problem, but will increase the driver power dissipation. A series resistor from 27 Ω to 54 Ω (depending on the trace impedance and connection) placed near the driver will also eliminate over/under shoot without additional driver power dissipation.

For many applications, the serial interface pins (SCK, SDI, \overline{CS} , f_0) remain static during the conversion cycle and no degradation occurs. On the other hand, if an external oscillator is used (f_0 driven externally) it is active during the conversion cycle. Moreover, the digital filter rejection is minimal at the clock rate applied to f_0 . Care must be taken to ensure external inputs and reference lines do not cross this signal or run near it. These issues are avoided when using the internal oscillator.

Driving the Input and Reference

The input and reference pins of the LTC2494 are connected directly to a switched capacitor network. Depending on the relationship between the differential input voltage and the differential reference voltage, these capacitors are switched between these four pins. Each time a capacitor is switched between two of these pins, a small amount of charge is transferred. A simplified equivalent circuit is shown in Figure 12.

When using the LTC2494's internal oscillator, the input capacitor array is switched at 123kHz. The effect of the charge transfer depends on the circuitry driving the input/reference pins. If the total external RC time constant is less than 580ns the errors introduced by the sampling process are negligible since complete settling occurs.

Typically, the reference inputs are driven from a low impedance source. In this case, complete settling occurs even with large external bypass capacitors. The inputs (CH0 to CH15, COM), on the other hand, are typically driven from larger source resistances. Source resistances up to 10k

may interface directly to the LTC2494 and settle completely; however, the addition of external capacitors at the input terminals in order to filter unwanted noise (anti-aliasing) results in incomplete settling.

The LTC2494 offers two methods of removing these errors. The first is automatic differential input current cancellation (Easy Drive) and the second is the insertion of buffer between the MUXOUT and ADCIN pins, thus isolating the input switching from the source resistance.

Automatic Differential Input Current Cancellation

In applications where the sensor output impedance is low (up to $10\text{k}\Omega$ with no external bypass capacitor or up to 500Ω with $0.001\mu\text{F}$ bypass), complete settling of the input occurs. In this case, no errors are introduced and direct digitization is possible.

For many applications, the sensor output impedance combined with external input bypass capacitors produces RC time constants much greater than the 580ns required for 1ppm accuracy. For example, a 10k bridge driving a $0.1\mu\text{F}$ capacitor has a time constant an order of magnitude greater than the required maximum.

The LTC2494 uses a proprietary switching algorithm that forces the average differential input current to zero independent of external settling errors. This allows direct digitization of high impedance sensors without the need of buffers.

The switching algorithm forces the average input current on the positive input (I_{IN}^+) to be equal to the average input current in the negative input (I_{IN}^-). Over the complete conversion cycle, the average input current ($I_{IN}^+ - I_{IN}^-$) is zero. While the differential input current is zero, the common mode input current ($(I_{IN}^+ + I_{IN}^-)/2$) is proportional to the difference between the common mode input voltage ($V_{IN(CM)}$) and the common mode reference voltage ($V_{REF(CM)}$).

In applications where the input common mode voltage is equal to the reference common mode voltage, as in the case of a balanced bridge, both the differential and common mode input current are zero. The accuracy of the converter is not compromised by settling errors.

In applications where the input common mode voltage is constant but different from the reference common mode voltage, the differential input current remains zero while the common mode input current is proportional to the

2494fe

APPLICATIONS INFORMATION

difference between $V_{IN(CM)}$ and $V_{REF(CM)}$. For a reference common mode voltage of 2.5V and an input common mode of 1.5V, the common mode input current is approximately 0.74 μ A (in simultaneous 50Hz/60Hz rejection mode). This common mode input current does not degrade the accuracy if the source impedances tied to IN^+ and IN^- are matched. Mismatches in source impedance lead to a fixed offset error but do not effect the linearity or full-scale reading. A 1% mismatch in a 1k source resistance leads to a 74 μ V shift in offset voltage.

In applications where the common mode input voltage varies as a function of the input signal level (single-ended type sensors), the common mode input current varies proportionally with input voltage. For the case of balanced input impedances, the common mode input current effects are rejected by the large CMRR of the LTC2494, leading to little degradation in accuracy. Mismatches in source impedances lead to gain errors proportional to the difference between the common mode input and common mode reference. 1% mismatches in 1k source resistances lead to gain errors on the order of 15ppm. Based on the stability of the internal sampling capacitors and the accuracy of the internal oscillator, a one-time calibration will remove this error.

Figure 13. External Buffers Provide High Impedance Inputs and Amplifier Offsets are Automatically Cancelled.

In addition to the input sampling current, the input ESD protection diodes have a temperature dependent leakage current. This current, nominally 1nA (± 10 nA max) results in a small offset shift. A 1k source resistance will create a 1 μ V typical and a 10 μ V maximum offset voltage.

Automatic Offset Calibration of External Buffers/ Amplifiers

In addition to the Easy Drive input current cancellation, the LTC2494 enables an external amplifier to be inserted between the multiplexer output and the ADC input (see Figure 13). This is useful in applications where balanced source impedances are not possible. One pair of external buffers/amplifiers can be shared between all 17 analog inputs. The LTC2494 performs an internal offset calibration every conversion cycle in order to remove the offset and drift of the ADC. This calibration is performed through a combination of front end switching and digital processing. Since the external amplifier is placed between the multiplexer and the ADC, it is inside this correction loop. This results in automatic offset correction and offset drift removal of the external amplifier.

The LTC6078 is an excellent amplifier for this function. It operates with supply voltages as low as 2.7V and its noise level is 18nV/ $\sqrt{\text{Hz}}$. The Easy Drive input technology of the LTC2494 enables an RC network to be added directly to the output of the LTC6078. The capacitor reduces the magnitude of the current spikes seen at the input to the ADC and the resistor isolates the capacitor load from the op-amp output enabling stable operation.

Reference Current

Similar to the analog inputs, the LTC2494 samples the differential reference pins (REF^+ and REF^-) transferring small amounts of charge to and from these pins, thus producing a dynamic reference current. If incomplete settling occurs (as a function of the reference source resistance and reference bypass capacitance) linearity and gain errors are introduced.

For relatively small values of external reference capacitance ($C_{REF} < 1$ nF), the voltage on the sampling capacitor settles for reference impedances of many k Ω (if $C_{REF} =$

100pF up to 10k will not degrade the performance) (see Figures 14, 15).

In cases where large bypass capacitors are required on the reference inputs ($C_{REF} > 0.01\mu F$) full-scale and linearity errors are proportional to the value of the reference resistance. Every ohm of reference resistance produces a full-scale error of approximately 0.5ppm (while operating in simultaneous 50Hz/60Hz mode) (see Figures 16 and 17). If the input common mode voltage is equal to the reference common mode voltage, a linearity error of approximately 0.67ppm per 100Ω of reference resistance results (see Figure 18). In applications where the input and reference common mode voltages are different, the errors increase. A 1V difference in between common mode input and common mode reference results in a 6.7ppm INL error for every 100Ω of reference resistance.

Figure 18. INL vs Differential Input Voltage and Reference Source Resistance for $C_{REF} > 1\mu F$

APPLICATIONS INFORMATION

In addition to the reference sampling charge, the reference ESD protection diodes have a temperature dependent leakage current. This leakage current, nominally 1nA (± 10 nA max) results in a small gain error. A 100 Ω reference resistance will create a 0.5 μ V full-scale error.

Normal Mode Rejection and Anti-Aliasing

One of the advantages delta-sigma ADCs offer over conventional ADCs is on-chip digital filtering. Combined with a large oversample ratio, the LTC2494 significantly simplifies anti-aliasing filter requirements. Additionally, the input current cancellation feature allows external low pass filtering without degrading the DC performance of the device.

The SINC⁴ digital filter provides excellent normal mode rejection at all frequencies except DC and integer multiples of the modulator sampling frequency (f_S) (see Figures 19 and 20). The modulator sampling frequency is $f_S = 15,360$ Hz while operating with its internal oscillator and $f_S = F_{EOSC}/20$ when operating with an external oscillator of frequency F_{EOSC} .

When using the internal oscillator, the LTC2494 is designed to reject line frequencies. As shown in Figure 21, rejection nulls occur at multiples of frequency f_N , where f_N is determined by the input control bits FA and FB ($f_N = 50$ Hz or 60Hz or 55Hz for simultaneous rejection). Multiples of the modulator sampling rate ($f_S = f_N \cdot 256$) only reject noise to 15dB (see Figure 22), if noise sources are present at these frequencies anti-aliasing will reduce their effects.

APPLICATIONS INFORMATION

The user can expect to achieve this level of performance using the internal oscillator, as shown in Figures 23, 24 and 25. Measured values of normal mode rejection are shown superimposed over the theoretical values in all three rejection modes.

Traditional high order delta-sigma modulators suffer from potential instabilities at large input signal levels. The proprietary architecture used for the LTC2494 third order modulator resolves this problem and guarantees stability with input signals 150% of full-scale. In many industrial applications, it is not uncommon to have microvolt level signals superimposed over unwanted volt level error sources with several volts of peak-to-peak noise. Figures 26 and 27 show measurement results for the rejection of a 7.5V peak-to-peak noise source (150% of full-scale) applied to the LTC2494. From these curves, it is shown that the rejection performance is maintained even in extremely noisy environments.

Using the 2x speed mode of the LTC2494 alters the rejection characteristics around DC and multiples of f_s . The device bypasses the offset calibration in order to increase the output rate. The resulting rejection plots are shown in Figures 28 and 29. 1x type frequency rejection can be achieved using the 2x mode by performing a running average of the conversion results (see Figure 30).

Output Data Rate

When using its internal oscillator, the LTC2494 produces up to 15 samples per second (sps) with a notch frequency of 60Hz. The actual output data rate depends upon the length of the sleep and data output cycles which are controlled by the user and can be made insignificantly short. When operating with an external conversion clock (f_0 connected to an external oscillator), the LTC2494 output data rate can be increased. The duration of the conversion cycle is $41036/f_{EOSC}$. If $f_{EOSC} = 307.2\text{kHz}$, the converter behaves as if the internal oscillator is used.

An increase in f_{EOSC} over the nominal 307.2kHz will translate into a proportional increase in the maximum output data rate (up to a maximum of 100sps). The increase in output rate leads to degradation in offset, full-scale error, and effective resolution as well as a shift in frequency rejection. When using the integrated temperature sensor, the internal

oscillator should be used ($f_0 = 0$) or an external oscillator applied to f_0 , f_{EOSC} , should be set to 307.2kHz Max.

A change in f_{EOSC} results in a proportional change in the internal notch position. This leads to reduced differential mode rejection of line frequencies. The common mode

rejection of line frequencies remains unchanged, thus fully differential input signals with a high degree of symmetry on both the IN^+ and IN^- pins will continue to reject line frequency noise.

An increase in f_{EOSC} also increases the effective dynamic input and reference current. External RC networks will continue to have zero differential input current, but the time required for complete settling (580ns for $f_{EOSC} = 307.2\text{kHz}$) is reduced, proportionally.

Once the external oscillator frequency is increased above 1MHz (a more than 3x increase in output rate) the effectiveness of internal auto calibration circuits begins to degrade. This results in larger offset errors, full-scale errors and decreased resolution (see Figures 31 to 38).

PACKAGE DESCRIPTION

UHF Package
38-Lead Plastic QFN (5mm × 7mm)
 (Reference LTC DWG # 05-08-1701 Rev C)

RECOMMENDED SOLDER PAD LAYOUT
 APPLY SOLDER MASK TO AREAS THAT ARE NOT SOLDERED

NOTE:

1. DRAWING CONFORMS TO JEDEC PACKAGE OUTLINE M0-220 VARIATION WHKD
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.20mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE
